My PhD

$$c = aQ^{-b}$$

b

(Zhi et al., 2019)

C_{SW} / C_{GW}

Vertical connectivity
vs.
hydrological status

How much of this complexity could we observe?

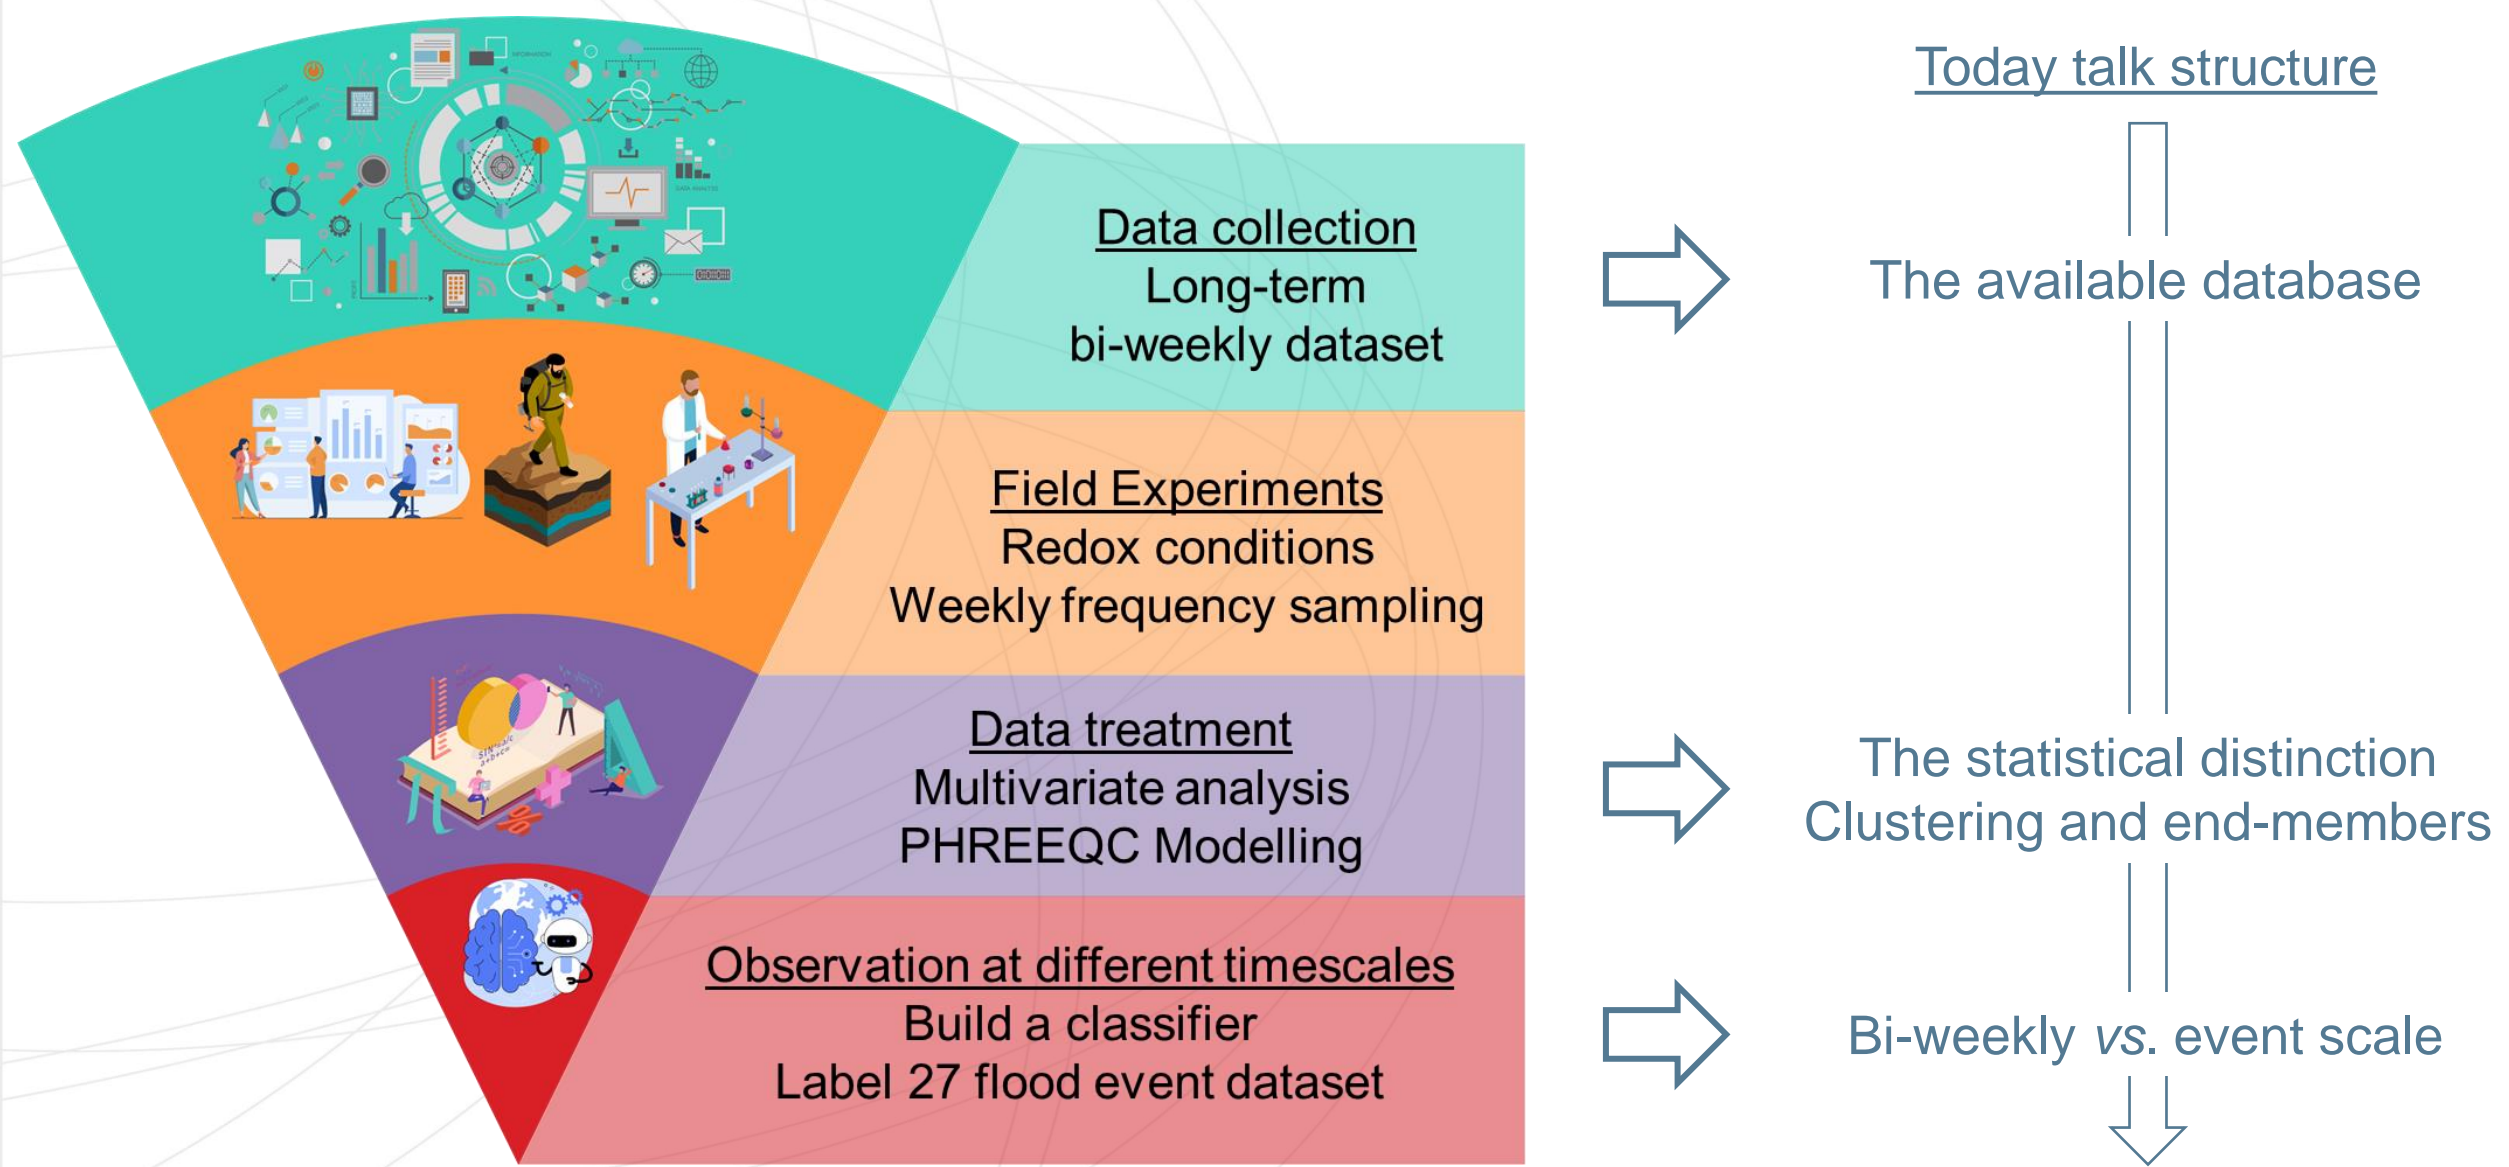

- Water chemistry will be stratified with depth due to vertical connectivity
- Relative contribution of end members/mixture change as a function of hydrological state

1

Compile a sufficiently large **dataset**

2

Observe "**unseen flowlines**" or endmembers

- area 45 ha
- altitude 450–500m asl
- mean precipitation 800 mm

Structure of the regolith: a polygenetic system

- Soil (70cm deep) *Haplic cambisol (Dystric, skeletal) from loamy PPSD*
- Primary plateau *saprolite (20m) + fractured slate*
- Secondary plateau *fractured slate*

Long-term bi-weekly sampling

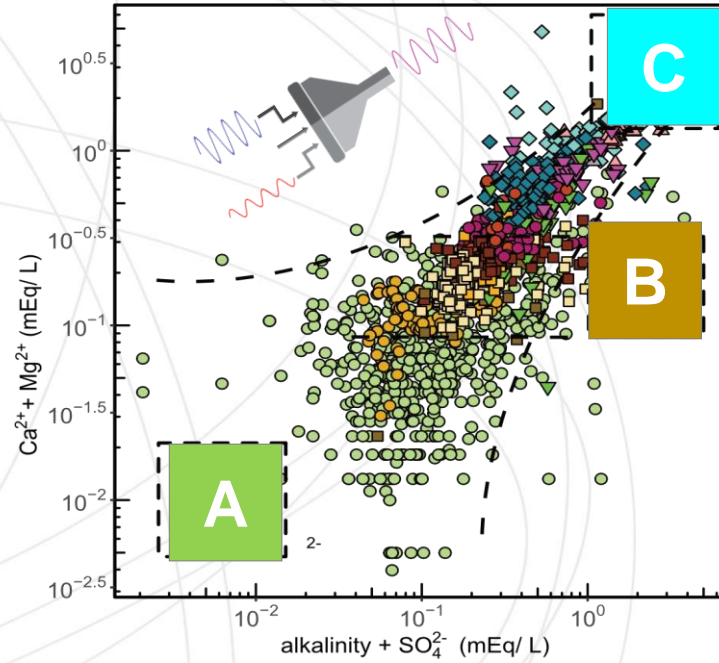

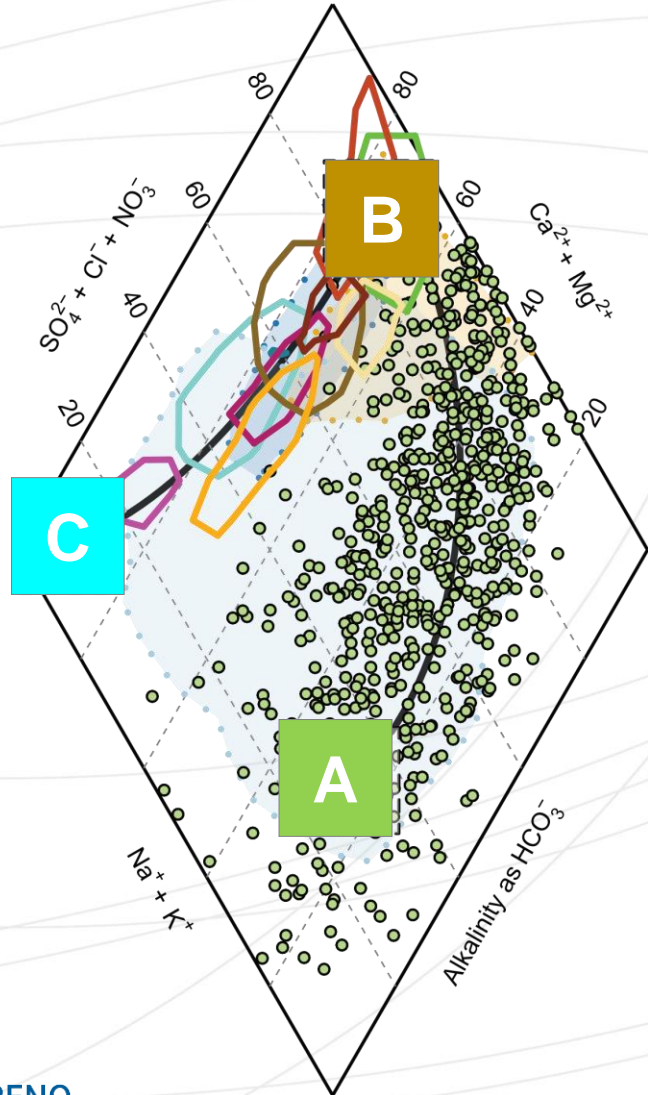

- 2009-20022 rain, throughfall, soil, GW, riparian, SW
- Standard water chemistry
- 2583 samples

Event-scale sampling

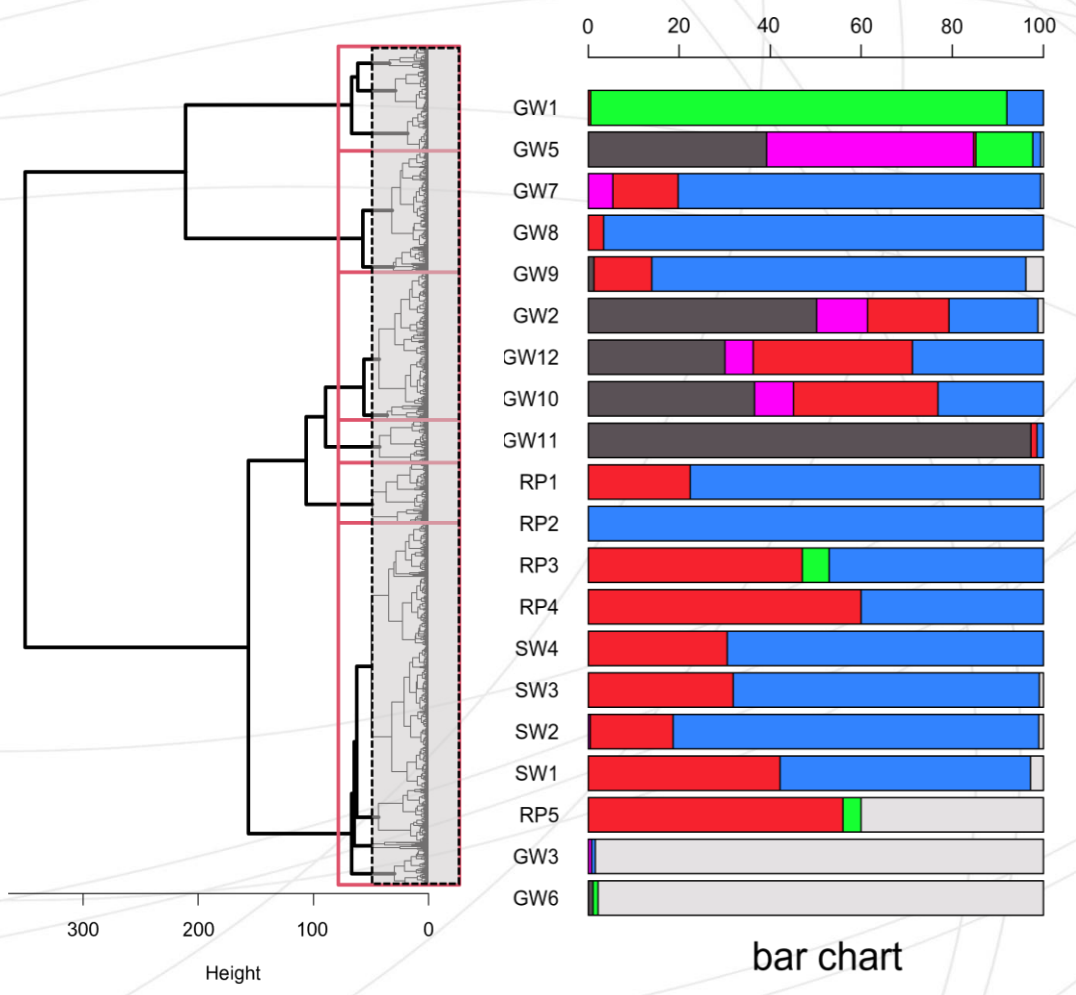

- 2005-20022 27 flood events
- Every 1h 5 – 40 samples

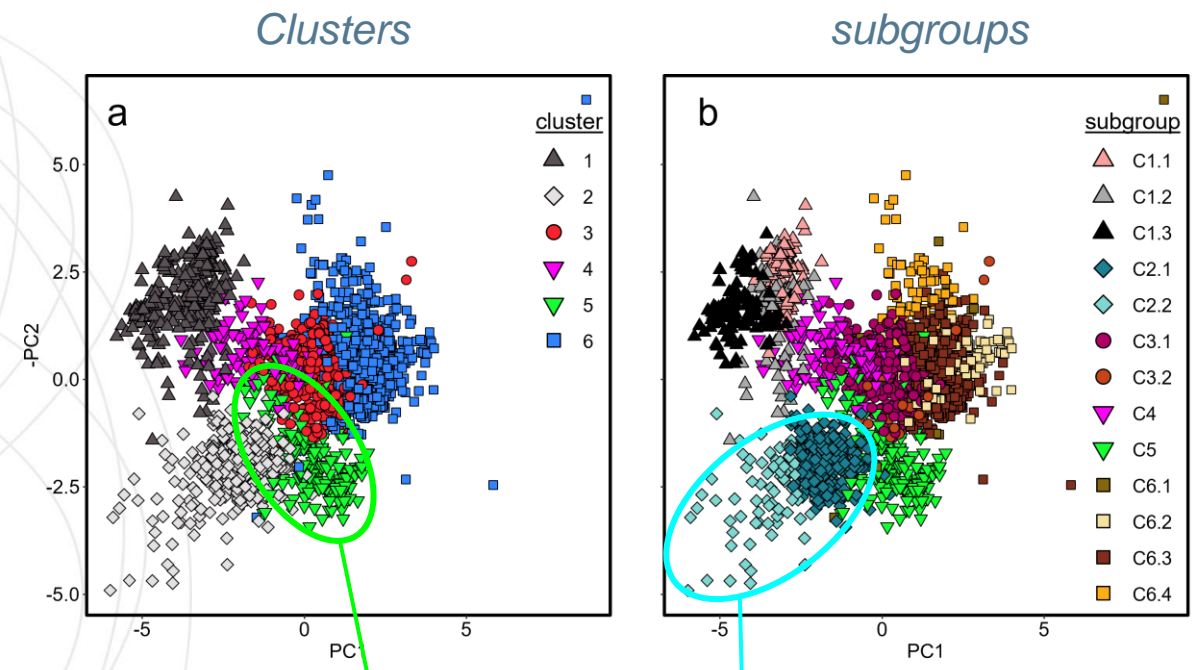

Vertical connectivity of biogeochemical processes

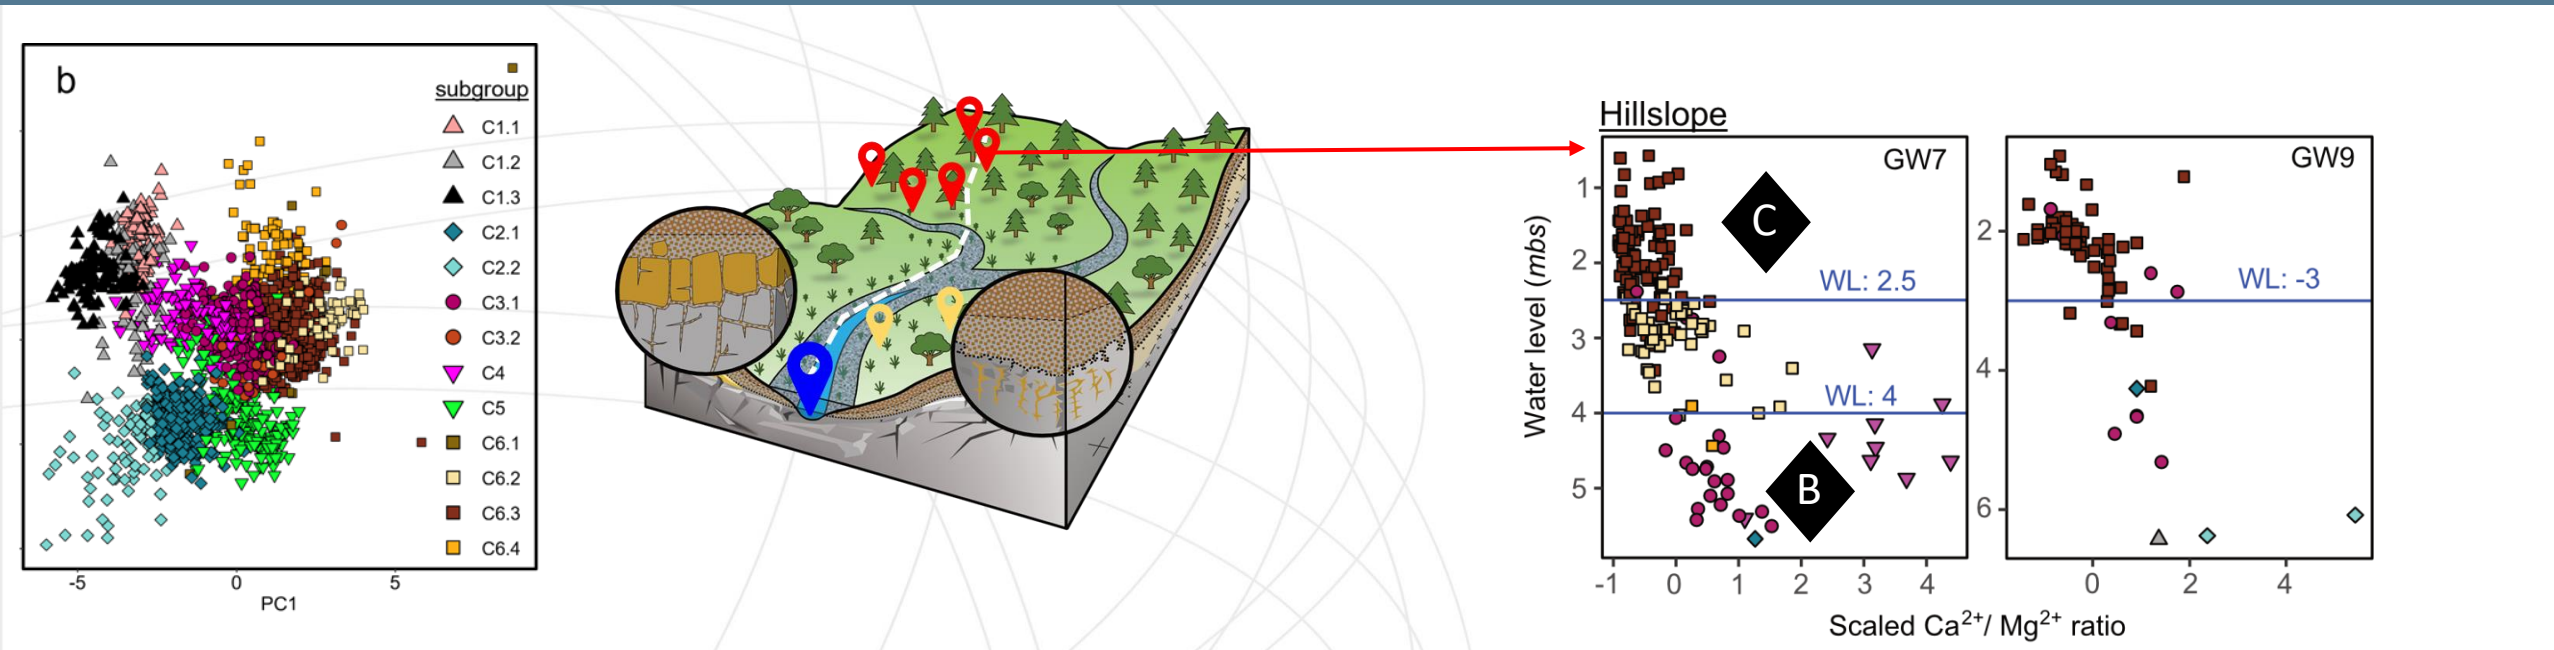

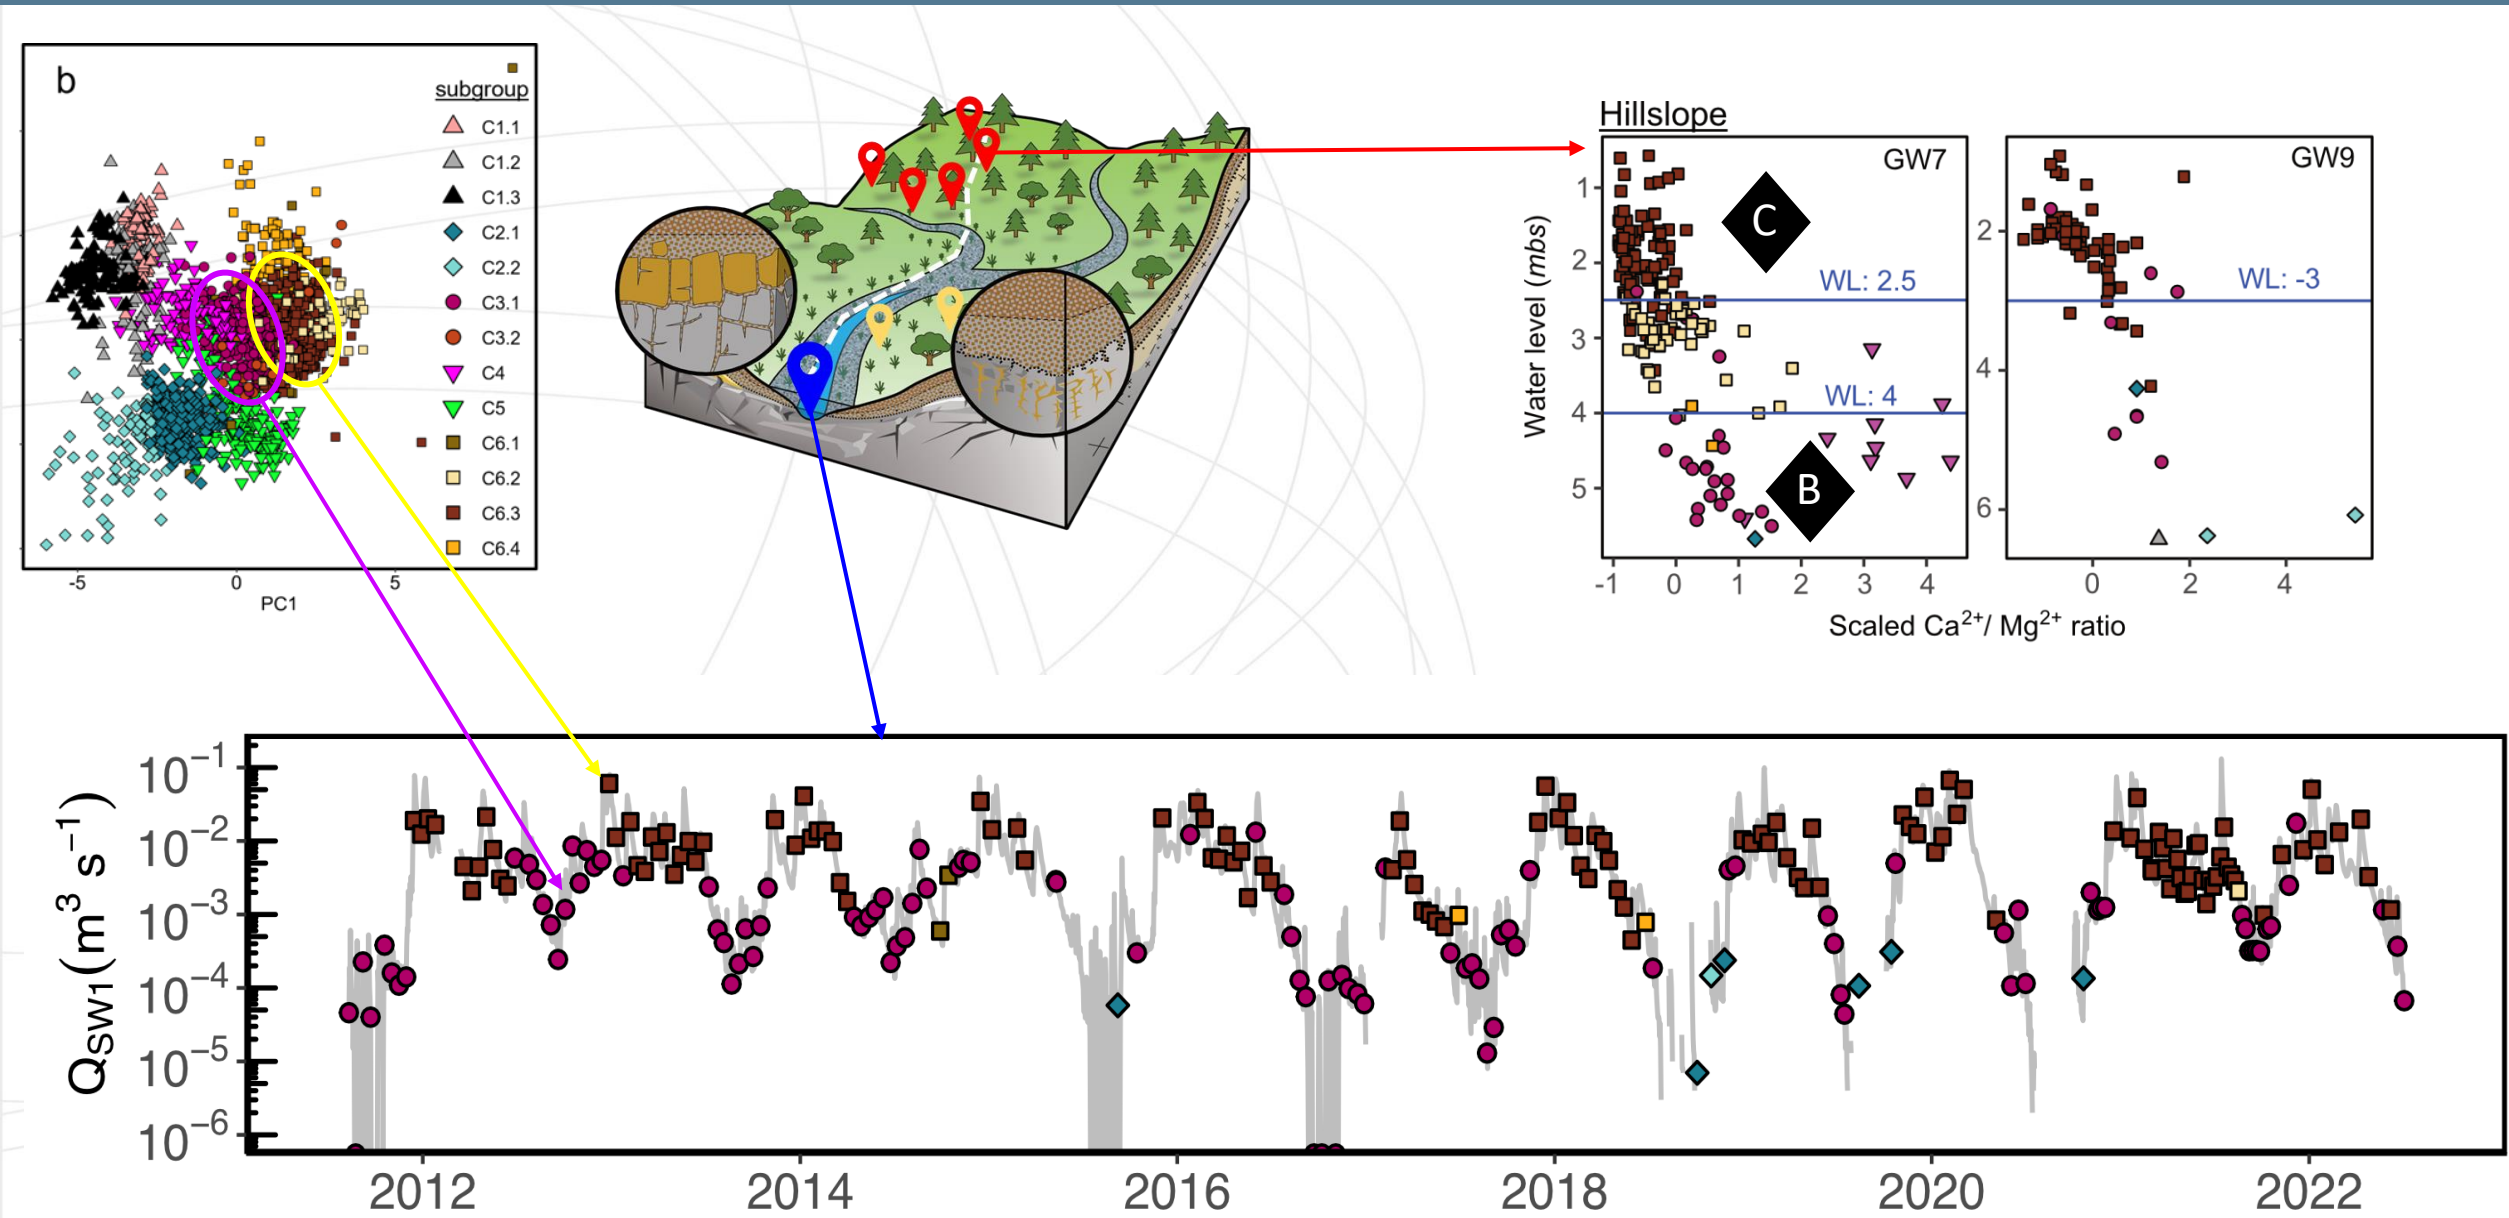

1. Hierarchical Cluster Analysis

2. Principal Component Analysis

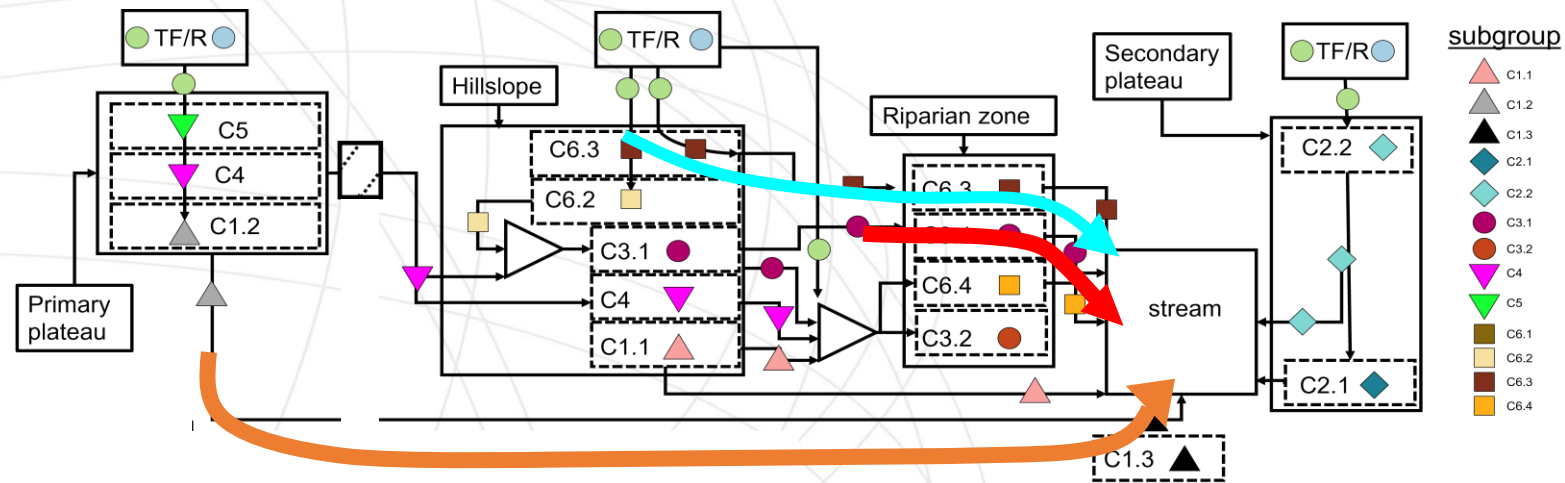

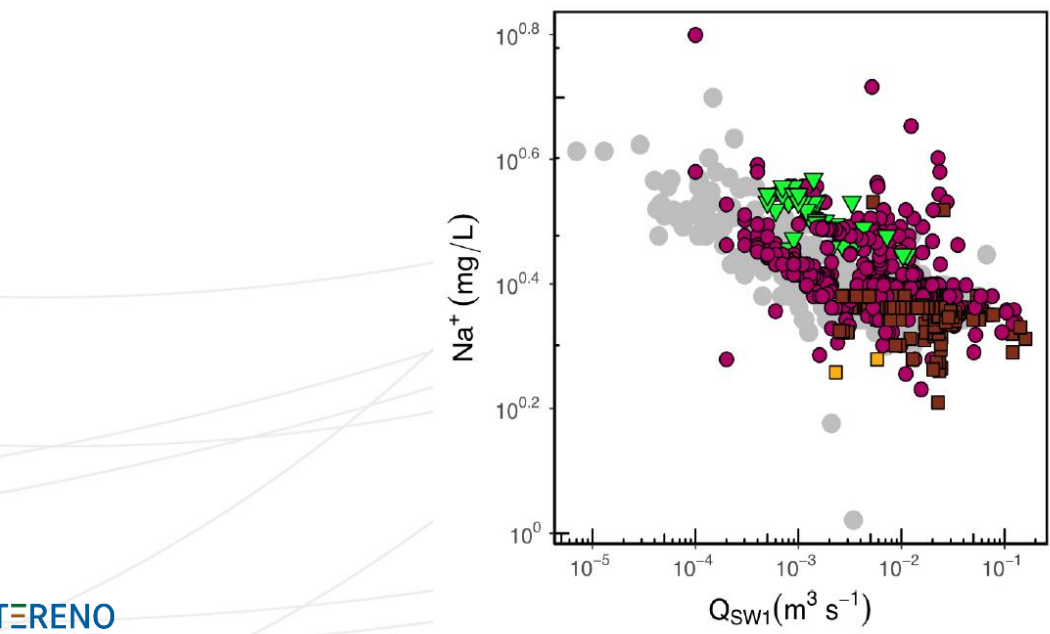

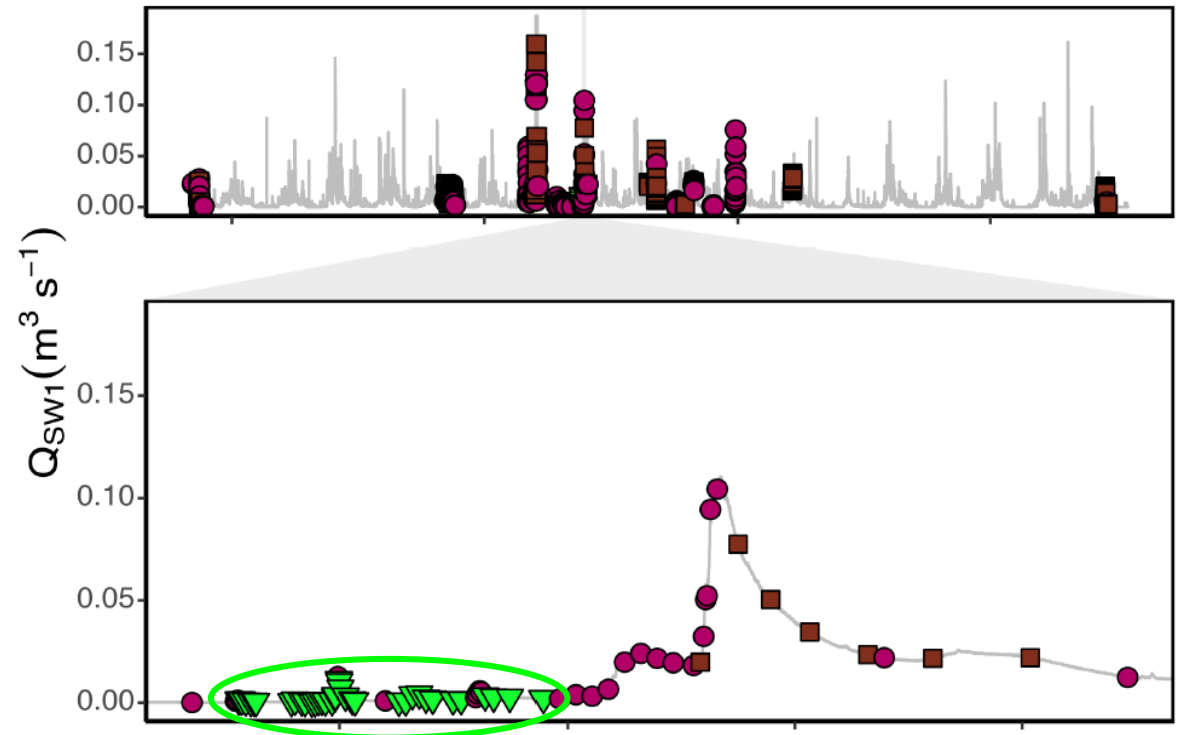

$$c = aQ^{-b}$$

BIG_flood9 2011-11-30 11:00:00 to 2011-12-29 06:00:00

Wrap up

1. Access to a large dataset that has SW and GW a new approach to an old problem could be applied

- *HCA and PCA, hidden end members could be identified and studied*
- *look beyond near stream end members and identify potentially deeper end members*

2. Are we observing end-members?

- *Cluster validation based on PHREEQC inverse modelling*

3. And now....

- Quantify the water fluxes related to the observed clusters/flowlines
- New consideration of the real weathering processes that contribute to stream/river chemistry
